PURPOSE: The purpose of this study was to identify the relationship between depression, perceived stress, fatigue and anger in clinical nurses. METHOD: A descriptive survey was conducted using a convenient sample. Data was collected by questionnaires from four hundred clinical nurses who worked at a university hospital. Radloff's CES-D for depression, Cohen, Kamarck & Merremelstein's Perceived Stress Scale, VAS for Fatigue, and Spielberger's STAXI for anger were used. The data was analyzed using the pearson correlation coefficient, students' t-test, ANOVA, and stepwise multiple regression with SPSS/WIN 12.0. RESULT: The depression of clinical nurses showed a significantly positive correlation to perceived stress ($r=.360$, $p=.000$), mental fatigue ($r=.471$, $p=.000$), physical fatigue ($r=.350$, $p=.000$), trait anger ($r=.370$, $p=.000$), anger-in expression ($r=.231$, $p=.000$), and anger-control expression ($r=.120$, $p=.016$). There was a negative correlation between depression and age ($r=-.146$, $p=.003$). The mean score of depression of nurses, 26, was a very high score and 40.8% of clinical nurses were included in a depression group. The main significant predictors influencing depression of clinical nurses were mental fatigue, trait anger, perceived stress, anger-in expression, and state anger, which explained about 32.7%. CONCLUSION: These results indicate that clinical nurses with a high degree of perceived stress, mental fatigue and anger-in expression are likely to be depressed.
